Applied Machine Learning

Lecture: 7-1
Model Evaluation

Ekarat Rattagan, Ph.D.

Slides adapted from Andrew NG, Eric Eaton, Raquel Urtasun, and Patrick Winston

Outline

- 7.1 Machine learning diagnostic
- 7.2 Model selection & evaluation
- 7.3 Diagnosing bias vs. variance
- 7.4 Regularization and bias/variance
- 7.5 Learning curves
- 7.6 Error metrics
- 7.7 Imbalanced data

7.2 Model selection & evaluation

Model Selection

Model selection: estimating the performance of different models in order to choose the best one.

1.
$$h_{\theta}(x) = \theta_0 + \theta_1 x$$

2.
$$h_{\theta}(x) = \theta_0 + \theta_1 x + \theta_2 x^2$$

3.
$$h_{\theta}(x) = \theta_0 + \theta_1 x + \dots + \theta_3 x^3$$

$$\vdots$$

10.
$$h_{\theta}(x) = \theta_0 + \theta_1 x + \dots + \theta_{10} x^{10}$$

Which one to choose? how a model generalizes to unseen test data.

Model Evaluation

- A part of the model development process to find the best model
- Two methods of evaluating models are
 - 1. Hold-out
 - 2. Cross validation

1. Hold-out method

Size	Price	_
2104	400	$(x^{(1)}, y^{(1)})$
1600	330	$(x^{(2)}, y^{(2)})$

>>> X_test
array([[2, 3],
    [8, 9]])
>>> y_test
[1, 4]
```

1. Hold-out method

- Learn parameter θ from training data (70%)
- Compute test set (30%)

$$J_{test}(\theta) = \frac{1}{2m_{test}} \sum_{i=1}^{m_{test}} (h_{\theta}(x_{test}^{(i)}) - y_{test}^{(i)})^2$$

1. Hold-out method

Method	Advantage	Disadvantage
1. Holdout	 Simple Takes no longer to compute	Waste data (30% in this slide)Its evaluation can have a high error

2. Cross validation

2. Cross-Validation

			$(x_{test}^{(m_{test})}, y_{test}^{(m_{test})})$

Train/validation/test error

Training error:

$$J_{train}(\theta) = \frac{1}{2m} \sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)})^2$$

Cross Validation error:

$$J_{cv}(\theta) = \frac{1}{2m_{cv}} \sum_{i=1}^{m_{cv}} (h_{\theta}(x_{cv}^{(i)}) - y_{cv}^{(i)})^2$$

Test error:

$$J_{test}(\theta) = \frac{1}{2m_{test}} \sum_{i=1}^{m_{test}} (h_{\theta}(x_{test}^{(i)}) - y_{test}^{(i)})^{2}$$

2. Cross Validation (K-fold)

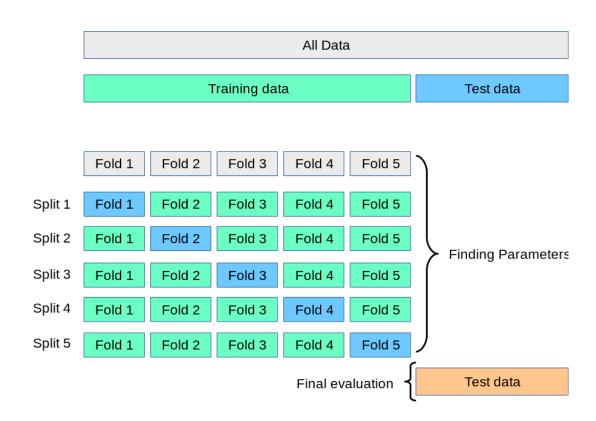

Figure from Hands-on Machine Learning

The training set is divided into k subsets, and the **holdout method** is repeated k times.

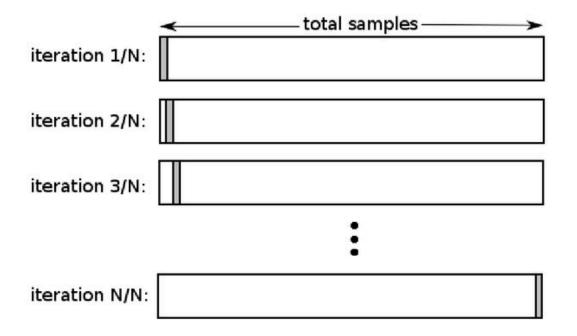

Each time, one of the k subsets is used as the test set and the other k-1 subsets are put together to form a training set.

Then the average error across all k trials is computed.

Evaluation method

Method	Advantage	Disadvantage
1. Holdout	SimpleLow computation	Waste data (30% in this slide)Its evaluation can have a high variance
2. Cross validation	 Every data point gets to be in a test set exactly once, and gets to be in a training set k-1 times. The variance of the resulting estimate is reduced as k is increased 	High computation

LOOCV (Leave-one-out Cross Validation)

K-fold cross validation taken to its logical extreme, with K equal to N.

```
>>> from sklearn.model_selection import LeaveOneOut
>>> X = [1, 2, 3, 4]
>>> loo = LeaveOneOut()
>>> for train, test in loo.split(X):
...     print("%s %s" % (train, test))
[1 2 3] [0]
[0 2 3] [1]
[0 1 3] [2]
[0 1 2] [3]
```

Evaluation method

Method	Advantage	Disadvantage
1. Holdout	SimpleLow computation	Waste data (30% in this slide)Its evaluation can have a high variance
	• Every data point gets to be in a test set exactly once, and gets to be in a training set k-1 times.	High computation
2. Cross validation	• The variance of the resulting estimate is reduced as <i>k</i> is increased	
3. Leave-One-Out	Does not waste data	High computation

7.4 Diagnosing bias vs. variance

Machine learning diagnostic

Suppose you have implemented regularized linear regression to predict housing prices.

$$J(\theta) = \frac{1}{2m} \left[\sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)})^2 + \lambda \sum_{j=1}^{m} \theta_j^2 \right]$$

However, when you test your hypothesis on a new set of houses, you find that it makes unacceptably large errors in its predictions. What should you try next?

- Get more training examples
- Try smaller sets of features
- Try getting additional features
- Try adding polynomial features $(x_1^2, x_2^2, x_1x_2, \text{etc.})$
- Try decreasing λ
- Try increasing λ

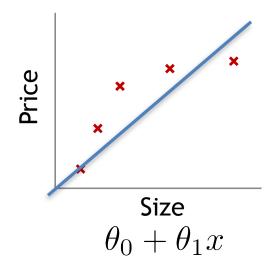

Machine learning diagnostic:

Diagnostic:

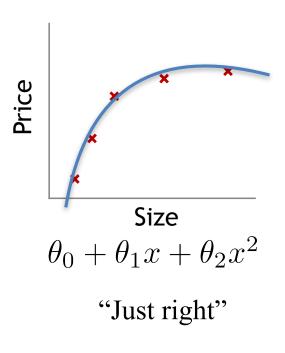

A test that you can run to gain insight what is/isn't working with a learning algorithm, and gain guidance as to how best to improve its performance.

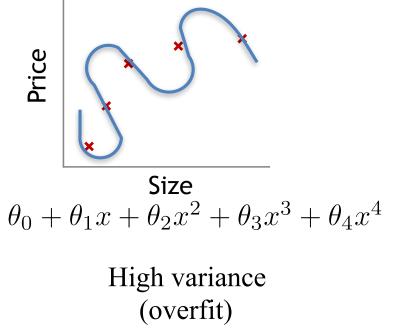

Diagnostics can take time to implement, but doing so can be a very good use of your time.

Bias/variance

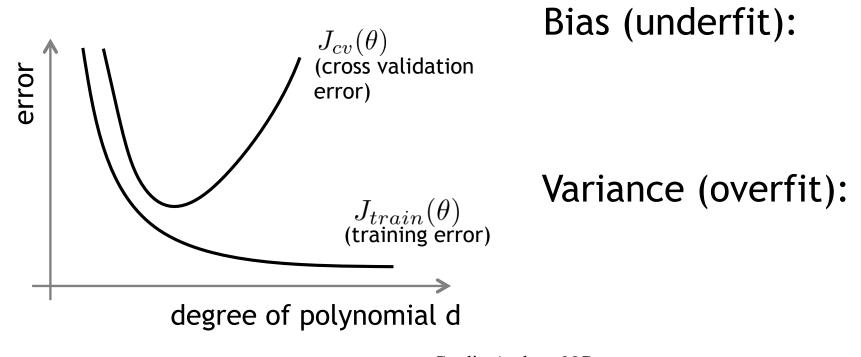

High bias (underfit)

Diagnosing bias vs. variance

Suppose your learning algorithm is performing less well than you were hoping ($J_{cv}(\theta)$ or $J_{test}(\theta)$ is high.). Is it a bias problem or a variance problem?

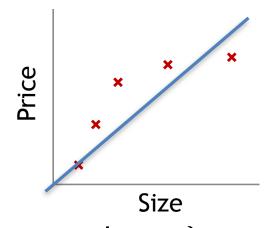

7.5 Regularization and bias/variance

Linear regression with regularization

Model:
$$h_{\theta}(x) = \theta_0 + \theta_1 x + \theta_2 x^2 + \theta_3 x^3 + \theta_4 x^4$$

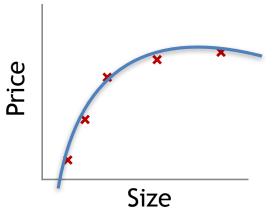

$$J(\theta) = \frac{1}{2m} \sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)})^2 + \frac{\lambda}{2m} \sum_{j=1}^{m} \theta_j^2$$

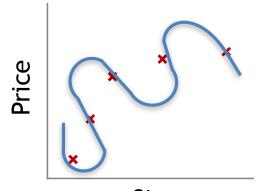

Large λ High bias (underfit)

$$\lambda = 10000. \ \theta_1 \approx 0, \theta_2 \approx 0, \dots$$

$$h_{\theta}(x) \approx \theta_0$$

Intermediate λ "Just right"

Size Small λ High variance (overfit)

Choosing the regularization parameter λ

$$h_{\theta}(x) = \theta_{0} + \theta_{1}x + \theta_{2}x^{2} + \theta_{3}x^{3} + \theta_{4}x^{4}$$

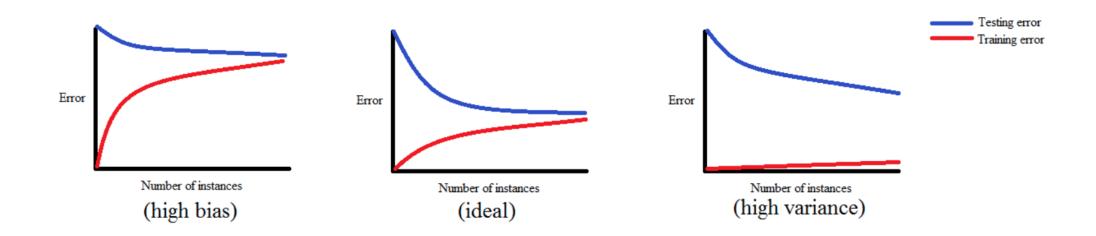

$$J(\theta) = \frac{1}{2m} \sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)})^{2} + \frac{\lambda}{2m} \sum_{j=1}^{n} \theta_{j}^{2}$$

$$J_{train}(\theta) = \frac{1}{2m} \sum_{i=1}^{m} (h_{\theta}(x^{(i)}) - y^{(i)})^{2}$$

$$J_{cv}(\theta) = \frac{1}{2m_{cv}} \sum_{i=1}^{m_{cv}} (h_{\theta}(x_{cv}^{(i)}) - y_{cv}^{(i)})^{2}$$

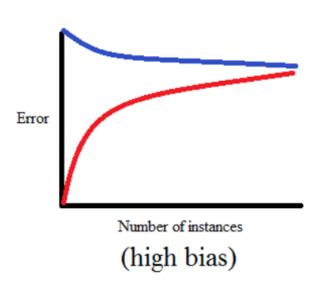

7.6 Learning curves

Error VS #Training data

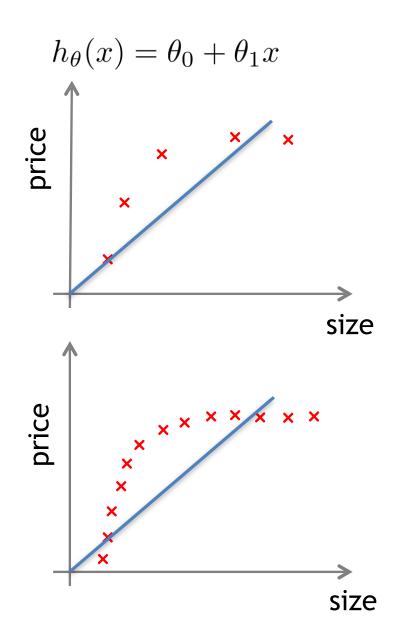

https://rmartinshort.jimdofree.com/2019/02/17/overfitting-bias-variance-and-leaning-curves/

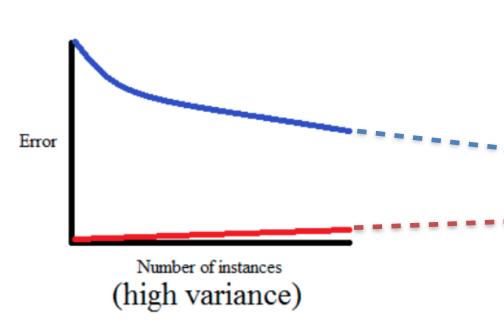

High bias

If a learning algorithm is suffering from high bias, getting more training data will not (by itself) help much.

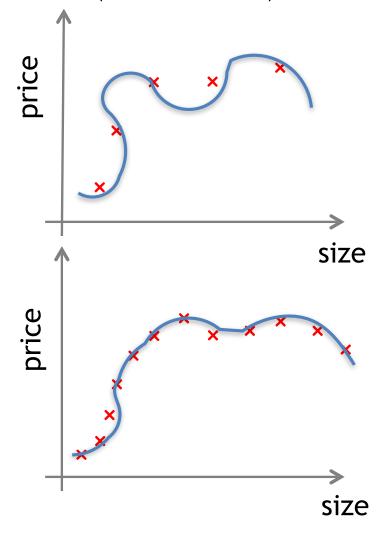

High variance

If a learning algorithm is suffering from high variance, getting more training data is likely to help.

$$h_{\theta}(x) = \theta_0 + \theta_1 x + \dots + \theta_{100} x^{100}$$
 (and small λ)

Debugging a learning algorithm:

Suppose you have implemented regularized linear regression to predict housing prices. However, when you test your hypothesis in a new set of houses, you find that it makes unacceptably large errors in its prediction. What should you try next?

- Get more training examples
- Try smaller sets of features
- Try getting additional features
- Try adding polynomial features $(x_1^2, x_2^2, x_1x_2, \text{etc})$
- Try decreasing λ
- Try increasing λ

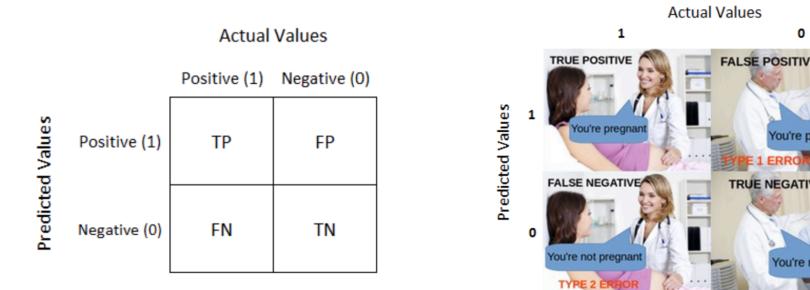

7.6 Error metrics

Error metrics

- Confusion Matrix
- Precision , Recall , and Accuracy
- F1-score
- ROC AUC Curve and score

Confusion Matrix

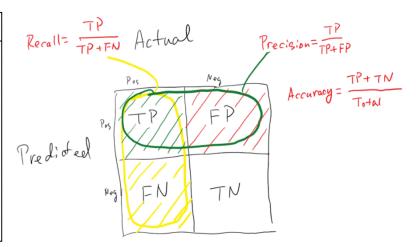

- A performance measurement for ML classification

https://towardsdatascience.com/understanding-confusion-matrix-a9ad42dcfd62

Confusion Matrix

у	y pred	output for threshold 0.6	Recall	Precision	Accuracy
0	0.5	0			
1	0.9	1			
0	0.7	1			
1	0.7	1	1/2	2/3	4/7
1	0.3	0			
0	0.4	0			
1	0.5	0			

https://towardsdatascience.com/understanding-confusion-matrix-a9ad42dcfd62

Precision/Recall

y = 1 in presence of rare class that we want to detect

Precision

(Of all patients where we predicted y = 1, what fraction actually has cancer?)

Recall

(Of all patients that actually have cancer, what fraction did we correctly detect as having cancer?)

Trading off precision and recall

Logistic regression: $0 \le h_{\theta}(x) \le 1$

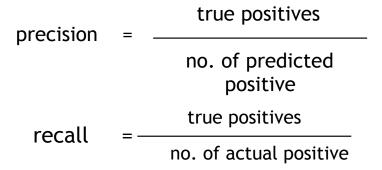

Predict 1 if $h_{\theta}(x) \geq 0.5$

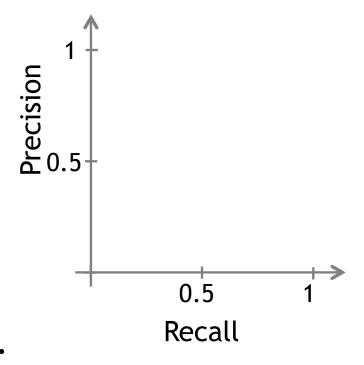

Predict 0 if $h_{\theta}(x) < 0.5$

Suppose we want to predict y=1 (cancer) only if very confident.

Suppose we want to avoid missing too many cases of cancer (avoid false negatives).

More generally: Predict 1 if $h_{\theta}(x) \geq$ threshold.

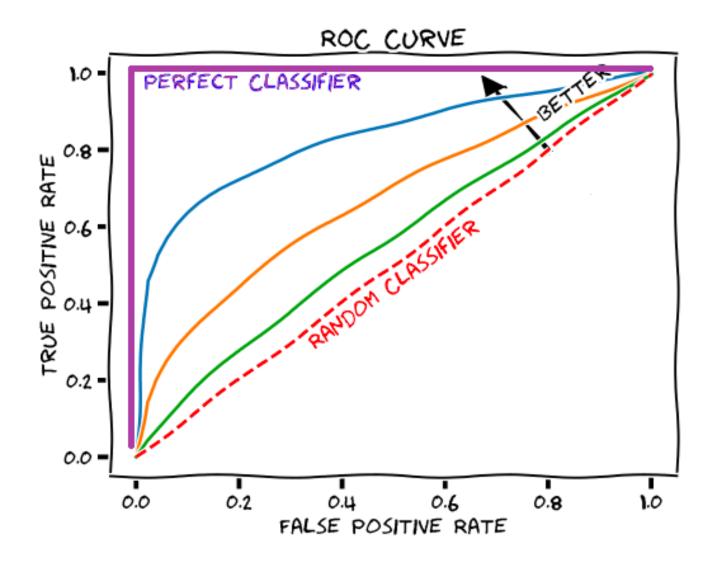

F₁ Score (F score)

How to compare precision/recall numbers?

	Precision(P)	Recall (R)
Algorithm 1	0.5	0.4
Algorithm 2	0.7	0.1
Algorithm 3	0.02	1.0

Average: $\frac{P+R}{2}$

 F_1 Score: $2\frac{PR}{P+R}$
